

### **REMARKS**

The present Amendment amends claims 1-16, and no claims are canceled or added. Therefore, the present application has pending claims 1-16.

#### **Information Disclosure Statement**

An Information Disclosure Statement (IDS) was filed on February 14, 2008. Although the Examiner returned a copy of Form PTO-1449, the Examiner did not initial the Ishibashi reference listed under "Other Documents" on the Form PTO-1449. Therefore, Applicants respectfully request the Examiner to initial the Ishibashi reference and return the enclosed copy of the Form PTO-1449 to indicate that the document has been considered.

#### **Claim Objections**

Claim 9 stands objected to due to informalities noted by the Examiner. Amendments were made to claim 9 to correct the informalities. Therefore, this objection is overcome and should be withdrawn.

#### **35 U.S.C. §102 Rejections**

##### **Claims 1-7 and 16**

Claims 1-7 and 16 stand rejected under 35 U.S.C. §102(e) as being anticipated by U. S. Patent Publication No. 2003/0174718 to Sampath et al. ("Sampath"). This rejection is traversed for the following reasons. Applicants submit that the features of the present invention as now more clearly recited in claims 1-7 and 16 are not taught or suggested by Sampath whether taken individually or in combination any of the other references of record. Therefore, Applicants respectfully request the Examiner to reconsider and withdraw this rejection.

Amendments were made to the claims to more clearly describe features of the present invention. Specifically, amendments were made to the claims to more clearly recite that the present invention is directed to a network authentication apparatus, a network authentication system and a switch apparatus as recited, for example, in independent claims 1 and 16.

The present invention, as recited in claim 1, and a similarly recited in claim 16, provides a network authentication apparatus. The apparatus includes a network interface unit connected with a network and that transmits/receives a packet. The apparatus also includes a packet relay unit that relays a received packet in accordance with a destination address of the received packet. The apparatus further includes a filtering processing unit that determines whether to relay the received packet to the packet relay unit or discard the packet. The filtering processing unit determines whether to relay or discard in accordance with; (a) one or more of a destination MAC (Media Access Control) address and a destination IPv6 (Internet Protocol version 6) address and a source MAC address; and (b) a source IPv6 interface ID, contained in the received packet. The prior art does not disclose all of these features.

The above described features of the present invention, as now more clearly recited in the claims, are not taught or suggested by any of the references of record, particularly Sampath, whether taken individually or in combination with any of the other references of record.

Sampath teaches a scalable packet filter for a network device. However, there is no teaching or suggestion in Sampath of the network authentication

apparatus, the network authentication system, or the switch apparatus as recited in claims 1 and 16 of the present invention.

Sampath discloses a network device for network communications. The device includes at least one data port interface, where the at least one data port interface supports at least one data port transmitting and receiving data and a CPU interface, and where the CPU interface is configured to communicate with a CPU. The network device also includes a memory communicating with the at least one data port interface, a memory management unit, the memory management unit including a memory interface for communicating data from the at least one data port interface and the memory and a communication channel, the communication channel for communicating data and messaging information between the at least one data port interface, the CPU interface, the memory, and the memory management unit. The network device also includes a fast filtering processor, the fast filtering processor filtering packets coming into the at least one data port interface, and taking selective filter action on a particular packet of the packets based upon specified packet field values. The specified packet field values are obtained by applying a filter mask, obtained from a field table, to the particular packet and the selective filter action is obtained from a policy table based on the specified packet field values.

One feature of the present invention, as recited in claim 1, and as similarly recited in claim 16, includes a filtering processing unit that determines whether to relay the received packet to the packet relay unit or discard the packet in accordance with: one or more of a destination MAC (Media Access Control) address and a destination IPv6 (Internet Protocol version 6) address and a source MAC address;

and a source IPv6 interface ID, contained in the received packet. Sampath does not disclose this feature.

For example, Sampath does not teach or suggest determining whether to relay or discard the packet in accordance with a source IPv6 interface ID, contained in the received packet, in the manner claimed. In the present invention, when a terminal device of a certain user moves and the network to be connected is changed, the terminal device newly receives distribution of an IP address from a DHCP (dynamic host configuration protocol) server, at the destination network. Therefore, the IP address of the terminal device would change when the terminal device moves. In some cases, the IP address cannot be used as a parameter of user authentication and filtering. It is an object of the present invention to solve this problem. It is another object of the present invention to secure both mobility and security, in a system where user authentication and filtering are performed (see, e.g., page 3, line 23 to page 4, line 4).

Accordingly, the present invention focuses on an interface ID, which is the lower 64 bits of an IPv6 address. This ID is an invariant ID even when the network to be connected is changed. One feature of the present invention is to use the interface ID as a parameter of user authentication and filtering. Thereby, the present invention has a great advantage that it is possible to secure both mobility and security in a system where user authentication and filtering are performed.

Sampath relates to a network device that includes a filtering processor, which filters packets based on a MAC address and an IP address. However, Sampath is not directed to mobility of a terminal, as in the present invention. For example, as described in paragraphs [0051] and [0052], and Table 3, Sampath merely discloses

a source IP address in a field table. However, Sampath does not disclose an interface ID of a source IPv6 address (i.e., a source IPv6 interface ID). When the source IP address of Sampath is used for filtering, even if the address is an IPv6 address, it is not possible to secure mobility because the source IP address includes a network ID (compare with Fig. 7 of the present invention). Sampath does not have the purpose or advantage of securing mobility, as in the present invention.

Sampath also discloses a "User Defined 16 bit field" in Table 3. However, this is not the same as the 64 bit interface ID of the source IPv6 address of the present invention. Accordingly, it is clear that Sampath does not set the interface ID of the source IPv6 address in the field. Therefore, it follows that Sampath does not teach or suggest securing both mobility and security in a system where user authentication and filtering are performed, and is different from the present invention.

Therefore, Sampath fails to teach or suggest "a filtering processing unit that determines whether to relay the received packet to the packet relay unit or discard the packet in accordance with: one or more of a destination MAC (Media Access Control) address and a destination IPv6 (Internet Protocol version 6) address and a source MAC address; and a source IPv6 interface ID, contained in the received packet" as recited in claim 1, and as similarly recited in claim 16.

Therefore, Sampath does not teach or suggest the features of the present invention, as recited in claims 1-7 and 16. Accordingly, reconsideration and withdrawal of the 35 U.S.C. §102(e) rejection of claims 1-7 and 16 as being anticipated by Sampath are respectfully requested.

The remaining references of record have been studied. Applicants submit that they do not supply any of the deficiencies noted above with respect to the references used in the rejection of claims 1-7 and 16.

**Claims 1-8 and 11-16**

Claims 1-8 and 11-16 stand rejected under 35 U.S.C. §102(b) as being anticipated by U. S. Patent Publication No. 2002/0016858 to Sawada et al. ("Sawada"). This rejection is traversed for the following reasons. Applicants submit that the features of the present invention as now more clearly recited in claims 1-8 and 11-16 are not taught or suggested by Sawada, whether taken individually or in combination any of the other references of record. Therefore, Applicants respectfully request the Examiner to reconsider and withdraw this rejection.

Amendments were made to the claims to more clearly describe features of the present invention. Specifically, amendments were made to the claims to more clearly recite that the present invention is directed to a network authentication apparatus, a network authentication system and a switch apparatus as recited, for example, in independent claims 1, 11 and 16.

The present invention, as recited in claim 1, and as similarly recited in claims 11 and 16, provides a network authentication apparatus. The apparatus includes a network interface unit connected with a network and that transmits/receives a packet. The apparatus also includes a packet relay unit that relays a received packet in accordance with a destination address of the received packet. The apparatus further includes a filtering processing unit that determines whether to relay the received packet to the packet relay unit or discard the packet. The filtering

processing unit determines whether to relay or discard in accordance with; (a) one or more of a destination MAC (Media Access Control) address and a destination IPv6 (Internet Protocol version 6) address and a source MAC address; and (b) a source IPv6 interface ID, contained in the received packet. The prior art does not disclose all of these features.

The above described features of the present invention, as now more clearly recited in the claims, are not taught or suggested by any of the references of record, particularly Sawada, whether taken individually or in combination with any of the other references of record.

Sawada teaches a communication apparatus for routing or discarding a packet sent from a user terminal. However, there is no teaching or suggestion in Sawada of the network authentication apparatus, the network authentication system, or the switch apparatus as recited in claims 1, 11 and 16 of the present invention.

Sawada discloses a packet communications apparatus. The apparatus includes a plurality of network interfaces (NIFs), a learned address table, a packet forwarding unit (PFU) and a processor for directive packets to change state (PDPCS). The learned address table contains information for identifying a NIF through which to send a packet. The PFU selects a port through which to forward a packet by referring to the learned address table, according to the state of the NIFs, and forwards or discards a packet received from a user terminal. The PDPCS receives a packet including a directive to change the state of a specific NIF to one of the connected state, disconnected state and stateless. The PDPCS changes the state of the specific NIF to one of the connected state, disconnected state and stateless, according to the directive in the packet.

One feature of the present invention, as recited in claim 1, and a similarly recited in claims 11 and 16, includes a filtering processing unit that determines whether to relay the received packet to the packet relay unit or discard the packet in accordance with: one or more of a destination MAC (Media Access Control) address and a destination IPv6 (Internet Protocol version 6) address and a source MAC address; and a source IPv6 interface ID, contained in the received packet. Sawada does not disclose this feature.

For example, Sawada does not teach or suggest determining whether to relay or discard a packet in accordance with a source IPv6 interface ID, contained in the received packet, in the manner claimed. As previously discussed, the present invention focuses on an interface ID, which is the lower 64 bits of an IPv6 address. This ID is an invariant ID even when the network to be connected is changed. One feature of the present invention is to use the interface ID as a parameter of user authentication and filtering. Thereby, the present invention has a great advantage that it is possible to secure both mobility and security in a system where user authentication and filtering are performed.

Sawada discloses a packet communication apparatus that performs an authentication and secures security based on a MAC address and an IP address. However, Sawada is not directed to the mobility of a terminal, and does not disclose using an interface ID of a source IPv6 address, as in the present invention.

To support the assertion that Sawada teaches a source ipv6 interface ID, the Examiner cites paragraphs [0116] and [0139]. However, neither the cited text nor any other portion of the Sawada, teaches or suggests the claimed feature. For example, as described in paragraph [0116], and as shown in Fig. 12, the filtering

table 1101 contains a destination address condition field 1201, a source address condition field 1202, and a forward/discard flag field 1203. In the destination address condition field 1201 and the source address condition field 1202, an IP address or data representing an “arbitrary” address is registered. There is no teaching or suggestion in Sawada that this IP address is a source IPv6 interface ID, as claimed.

As described in paragraph [0139], and as shown in Fig. 17, the filtering table 1607 contains entries in a MAC address field 1701, an IP address field 1702, and a connection port field 1703. There is no teaching or suggestion of a source IPv6 interface ID, in the manner claimed.

Therefore, Sawada fails to teach or suggest “a filtering processing unit that determines whether to relay the received packet to the packet relay unit or discard the packet in accordance with: one or more of a destination MAC (Media Access Control) address and a destination IPv6 (Internet Protocol version 6) address and a source MAC address; and a source IPv6 interface ID, contained in the received packet” as recited in claim 1, and as similarly recited in claims 11 and 16.

Therefore, Sawada does not teach or suggest the features of the present invention, as recited in claims 1-8 and 11-16. Accordingly, reconsideration and withdrawal of the 35 U.S.C. §102(b) rejection of claims 1-8 and 11-16 as being anticipated by Sawada are respectfully requested.

The remaining references of record have been studied. Applicants submit that they do not supply any of the deficiencies noted above with respect to the references used in the rejection of claims 1-8 and 11-16.

### **35 U.S.C. §103 Rejections**

Claims 8, 9 and 11-15 stand rejected under 35 U.S.C. §103(a) as being unpatentable over Sampath in view of U. S. Patent No. 6,442,588 to Clark et al. ("Clark"). This rejection is traversed for the following reasons. Applicants submit that the features of the present invention, as now more clearly recited in claims 8, 9 and 11-15, are not taught or suggested by Sampath or Clark, whether taken individually or in combination with each other in the manner suggested by the Examiner. Therefore, Applicants respectfully request the Examiner to reconsider and withdraw this rejection.

Claims 8 and 9 are dependent on claim 1. Therefore, Applicants submit that claims 8 and 9 are allowable for at least the same reasons as previously discussed regarding independent claim 1.

Regarding the remaining claims 11-15, amendments were made to the claims to more clearly describe features of the present invention. Specifically, amendments were made to the claims to more clearly recite that the present invention is directed to a network authentication system as recited, for example, in independent claim 11.

The present invention, as recited in claim 11, provides a network authentication system. The network authentication system includes an authentication server that receives an authentication request from an arbitrary information terminal device connected via a network and executing authentication based on predetermined information related to the arbitrary information terminal device. The network authentication system also includes a network node device connected to the network and that relays a packet received from the network. According to the present invention, the network node device includes a network interface unit connected with the network and that transmits/receives a packet, a

packet relay unit that relays a received packet in accordance with a destination address of the received packet, and a filtering processing unit that determines whether to relay the received packet to the packet relay unit or discard the packet. The filtering processing unit determines whether to relay or not in accordance with: (a) one or more of a destination MAC (Media Access Control) address and a destination IPv6 (Internet Protocol version 6) address and a source MAC address; and (b) a source IPv6 interface ID, contained in the received packet, where the filtering processing unit relays only a packet addressed to the authentication server to the packet relay unit, of packets sent from an arbitrary information terminal device that is not authenticated by the authentication server. The prior art does not teach or suggest all of these features.

The above described features of the present invention, as now more clearly recited in the claims, are not taught or suggested by any of the references of record. Specifically, the features are not taught or suggested by either Sampath or Clark, whether taken individually or in combination with each other.

As previously discussed, Sampath teaches a scalable packet filter for a network device. However, there is no teaching or suggestion in Sampath of the network authentication system as recited in claim 11 of the present invention.

One feature of the present invention, as recited in claim 11, includes a filtering processing unit that determines whether to relay the received packet to the packet relay unit or discard the packet in accordance with: one or more of a destination MAC (Media Access Control) address and a destination IPv6 (Internet Protocol version 6) address and a source MAC address; and a source IPv6 interface ID, contained in the received packet. Sampath does not disclose this feature.

For example, Sampath does not teach or suggest determining whether to relay or discard the packet in accordance with a source IPv6 interface ID, contained in the received packet, in the manner claimed. In the present invention, when a terminal device of a certain user moves and the network to be connected is changed, the terminal device newly receives distribution of an IP address from a DHCP (dynamic host configuration protocol) server, at the destination network. Therefore, the IP address of the terminal device would change when the terminal device moves. In some cases, the IP address cannot be used as a parameter of user authentication and filtering. It is an object of the present invention to solve this problem. It is another object of the present invention to secure both mobility and security, in a system where user authentication and filtering are performed (see, e.g., page 3, line 23 to page 4, line 4).

Accordingly, the present invention focuses on an interface ID, which is the lower 64 bits of an IPv6 address. This ID is an invariant ID even when the network to be connected is changed. One feature of the present invention is to use the interface ID as a parameter of user authentication and filtering. Thereby, the present invention has a great advantage that it is possible to secure both mobility and security in a system where user authentication and filtering are performed.

Sampath relates to a network device that includes a filtering processor, which filters packets based on a MAC address and an IP address. However, Sampath is not directed to mobility of a terminal, as in the present invention. For example, as described in paragraphs [0051] and [0052], and Table 3, Sampath merely discloses a source IP address in a field table. However, Sampath does not disclose an interface ID of a source IPv6 address (i.e., a source IPv6 interface ID). When the

source IP address of Sampath is used for filtering, even if the address is an IPv6 address, it is not possible to secure mobility because the source IP address includes a network ID (compare with Fig. 7 of the present invention). Sampath does not have the purpose or advantage of securing mobility, as in the present invention.

Sampath also discloses a "User Defined 16 bit field" in Table 3. However, this is not the same as the 64 bit interface ID of the source IPv6 address of the present invention. Accordingly, it is clear that Sampath does not set the interface ID of the source IPv6 address in the field. Therefore, it follows that Sampath does not teach or suggest securing both mobility and security in a system where user authentication and filtering are performed, and is different from the present invention.

Therefore, Sampath fails to teach or suggest "a filtering processing unit that determines whether to relay the received packet to the packet relay unit or discard the packet in accordance with: one or more of a destination MAC (Media Access Control) address and a destination IPv6 (Internet Protocol version 6) address and a source MAC address; and a source IPv6 interface ID, contained in the received packet" as recited in claim 11.

The above noted deficiencies of Sampath are not supplied by any of the other references of record, namely Clark, whether taken individually or in combination with each other. Therefore, combining the teachings of Sampath and Clark in the manner suggested by the Examiner still fails to teach or suggest the features of the present invention as now more clearly recited in the claims.

Clark teaches a method of administering a dynamic filtering firewall. However, there is no teaching or suggestion in Clark of the network authentication system as recited in claim 11 of the present invention.

Clark discloses a method of permitting a subscriber access to an online server complex operated by a particular online service provider (OSP). An IP communication request including a destination IP address and an origination IP address is received. The IP communication request is forwarded to a dynamic filtering firewall if the destination IP address corresponds to a service provided by the particular OSP. The origination IP address is compared with a table of stored authenticated IP addresses. The IP communication request is forwarded to the destination IP address if the origination IP address matches an IP address contained in the table.

One feature of the present invention, as recited in claim 11, includes a filtering processing unit that determines whether to relay the received packet to the packet relay unit or discard the packet in accordance with: one or more of a destination MAC (Media Access Control) address and a destination IPv6 (Internet Protocol version 6) address and a source MAC address; and a source IPv6 interface ID, contained in the received packet. Clark does not disclose this feature, and the Examiner does not rely upon Clark for teaching this feature.

Therefore, Clark fails to teach or suggest “filtering processing unit that determines whether to relay the received packet to the packet relay unit or discard the packet in accordance with: one or more of a destination MAC (Media Access Control) address and a destination IPv6 (Internet Protocol version 6) address and a source MAC address; and a source IPv6 interface ID, contained in the received packet” as recited in claim 11.

Both Sampath and Clark suffer from the same deficiencies, relative to the features of the present invention, as recited in the claims. Therefore, combining the

teachings of Sampath and Clark in the manner suggested by the Examiner does not render obvious the features of the present invention as now more clearly recited in the claims. Accordingly, reconsideration and withdrawal of the 35 U.S.C. §103(a) rejection of claims 8, 9 and 11-15 as being unpatentable over Sampath in view of Clark are respectfully requested.

The remaining references of record have been studied. Applicants submit that they do not supply any of the deficiencies noted above with respect to the references used in the rejection of claims 8, 9 and 11-15.

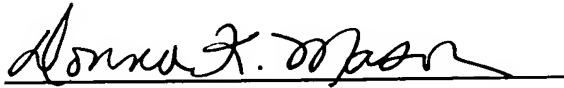

Claim 10 stands rejected under 35 U.S.C. §103(a) as being unpatentable over Sampath and further in view of U. S. Patent No. 7,051,365 to Bellovin. Claim 10 is dependent on claim 1. Therefore, claim 10 is allowable for at least the same reasons previously discussed regarding independent claim 1.

In view of the foregoing amendments and remarks, Applicants submit that claims 1-16 are in condition for allowance. Accordingly, early allowance of claims 1-16 is respectfully requested.

To the extent necessary, the Applicants petition for an extension of time under 37 CFR 1.136. Please charge any shortage in fees due in connection with the filing of this paper, including extension of time fees, or credit any overpayment of fees, to the deposit account of Mattingly, Stanger, Malur & Brundidge, P.C., Deposit Account No. 50-1417 (referencing Attorney Docket No. HAS-101).

Respectfully submitted,

MATTINGLY, STANGER, MALUR & BRUNDIDGE, P.C.
